

Sentiment Analysis of Amazon Reviews

In this project, I performed sentiment analysis on Amazon product reviews using Python. First, I cleaned the data by removing missing and duplicate reviews and kept only the required columns.

Then, I used the TextBlob library to calculate the polarity score of each review. Based on this score, I classified the reviews as Positive, Negative, or Neutral.

I also created visualizations such as a bar chart, pie chart, and a rating vs sentiment comparison to better understand the data.

From the analysis, I found that most reviews are positive, while negative and neutral reviews are fewer. I also observed that higher ratings are generally associated with positive sentiment, although some mismatches are present.

This project helped me understand how NLP can be used to analyze customer feedback.
